Abstract

Using the hypersingular integral equation method based on body force method, a planar crack in a three-dimensional transversely isotropic piezoelectric solid under mechanical and electrical loads is analyzed. This crack problem is reduced to solve a set of hypersingular integral equations. Compare with the crack problems in elastic isotropic materials, it is shown that for the impermeable crack, the intensity factors for piezoelectric materials can be obtained from those for elastic isotropic materials. Based on the exact analytical solution of the singular stresses and electrical displacements near the crack front, the numerical method of the hypersingular integral equation is proposed by the finite-part integral method and boundary element method, which the square root models of the displacement and electric potential discontinuities in elements near the crack front are applied. Finally, the numerical solutions of the stress and electric field intensity factors of some examples are given.

1. Introduction

The piezoelectric materials have coupled effects between the elastic and the electric fields, and have become of major interest as the functional materials such as actuators and sensors. It is possible to make a system of intelligent composite materials by combining these piezoelectric materials with structural materials. On the other hand, both electrical and mechanical disturbances are present in piezoelectric components, and the strength of the piezoelectric materials is weakened by the presence of defects such as voids and cracks. The reliability of these structures depends on the knowledge of applied mechanical and electric disturbances. When cracks are present, they may grow under service load and affect the performance of structures. Due to the disadvantage of brittleness and low fracture toughness of piezoelectric materials, a considerable number of research works have been carried out to investigate the fracture behavior (Deeg, 1980; Pak, 1990; Suo and
Kuo et al., 1992; Wang, 1992; Norris, 1994; Park and Sun, 1995; Shang et al., 2003; Kumar and Singh, 1996; Hill and Farris, 1998; McMeeking, 1999; Qin, 2001; Wang and Huang, 1995; Liu and Fan, 2001; Rajapakse and Xu, 2001; Khutoryansky and Sosa, 1995; Dunn and Wienecke, 1996; Daros and Antes, 2000; Chen and Lin, 1995; Wang and Zhang, 2005).

Because of mathematical difficulties to treat the coupled electromechanical fields in piezoelectricity, the majority of the literature concerning crack problems is based on two-dimensional assumptions. Comparatively, few exact solutions are available in the literature for three-dimensional crack problems in piezoelectric materials. Wang and Huang (1995) obtained the solution for an elliptical crack under uniform tractions and electric disturbance, if the plane of transversal isotropy is parallel to the crack. Closed-form solutions for other 3D crack configurations in an infinite piezoelectric body are yet to be found. Thus, to assess crack-like defects in piezoelectric materials under combined mechanical and electric loadings more efficiently, it is necessary to establish appropriate numerical tools. There are two important numerical methods. One is the finite element method (FEM), and another is the boundary element method (BEM). Shang et al. (2003) have analyzed penny-shaped and elliptical cracks subjected to combined mechanical tension and electric fields by FEM, and presented some numerical results of the stress intensity factors and energy release rates. BEM is a powerful tool for the solution of field problems of mathematical physics, since it offers some inherent advantages over FEM, like the discretization of the boundary only and an improved accuracy in flux calculations. Many publications have already been devoted to the development of fundamental solutions and BEM for piezoelectricity (Deeg, 1980, 2001, ), but only a very limited number of them deals with three-dimensional analyses, due to the problems involved resulting from the anisotropy of piezoelectric materials. A 3D Green’s function for static piezoelectricity and its derivatives have been presented by Deeg (1980) for piezoelectrics of general anisotropy. Dynamic piezoelectric Green’s functions have been presented by Norris (1994) in the frequency domain and by Khutoryansky and Sosa (1995) in the time domain. For the particular case of transversely isotropic piezoelectricity, Dunn and Wienecke (1996) for piezoelectrostatics, and Daros and Antes (2000) for transient analysis developed simplified expressions for the Green’s functions. BEM for static piezoelectricity with corresponding numerical results for 3D analysis has been presented by Chen and Lin (1995), and by Hill and Farris (1998). Wang and Zhang (2005) have applied the electrical field saturation model to the fracture prediction of piezoelectric materials containing electrically impermeable cracks, and obtained the stress intensity factor and the energy release rate in closed-form. Zhao and Shen et al. (1997) has investigated the crack problems in piezoelectric materials by BEM and hypersingular integral equation, and given a solution for circular crack. A set hypersingular integral equations and some numerical results for a planar crack in an infinite transversely isotropic piezoelectric media has been given by Chen (2003), in which the unknown function is approximated with a product of the fundamental density function and polynomials. Qin and Noda (2004) have derived a set of hypersingular integral equations of a three-dimensional crack problem in piezoelectric materials, and obtained the exact analytical solutions of the singular stresses and electrical displacements near the crack front in a transversely isotropic piezoelectric solid, but not given the numerical method and solutions.

In this paper, based on the exact analytical solution of the singular stresses and electrical displacements near the crack front, a numerical method for the crack problems in a three-dimensional transversely isotropic piezoelectric solid was proposed by the finite-part integral method and boundary element method. It is shown that for impermeable cracks, the numerical values of the dimensionless intensity factors of $K_I$ and $K_{IV}$ are equal to that of the dimensionless intensity factor of mode I for elastic isotropic materials.

**2. Basic of piezoelectricity**

The linear governing equations and constitutive relations for a piezoelectric material in static equilibrium can be expressed as two separate equations, one representing conservation of momentum and the other conservation of electric charge (Deeg, 1980; Pak, 1990; Suo and Kuo et al., 1992; Wang, 1992). To use these two equations in conjunction with the developed boundary integral equation method, they are combined into one. In these equations, lowercase indices $i,l$ can have values of 1, 2, or 3, and uppercase indices $I$ can take on values of 1, 2, 3, and 4. The modified governing equation for the piezoelectric material in static equilibrium can be written as (Deeg, 1980)
\[ \Sigma_{ij} + b_J = 0 \]  
where \( \Sigma_{ij} \) is the stress-electric displacement matrix, defined as
\[
\Sigma_{ij} = \begin{cases} 
\sigma_{ij} & \text{for } J = j = 1, 2, 3 \\
D_i & \text{for } J = 4 
\end{cases}
\]
and \( b_J \) is the body load (force and charge) column vector. A subscript comma denotes the partial differentiation. The combined constitutive equation is written as
\[
\Sigma_{ij} = E_{ijk}Z_{kl}
\]
where \( E_{ijk} \) is the electroelastic constant matrix
\[
E_{ijk} = \begin{cases} 
\varepsilon_{ijkl} & \text{for } J, K = 1, 2, 3 \\
\varepsilon_{ij} & \text{for } J = 1, 2, 3, K = 4 \\
\varepsilon_{kl} & \text{for } J = 4, K = 1, 2, 3 \\
-a_{kl} & \text{for } J = 4, K = 4 
\end{cases}
\]
and the strain-electric field matrix \( Z_{kl} \) takes the form
\[
Z_{kl} = \begin{cases} 
\varepsilon_{kl} & \text{for } K = k = 1, 2, 3 \\
\phi_{kl} & \text{for } K = 4 
\end{cases}
\]
In addition, \( U_K \) is the elastic displacement-electric potential matrix
\[
U_K = \begin{cases} 
u_k & \text{for } K = k = 1, 2, 3 \\
\phi & \text{for } K = 4 
\end{cases}
\]
where \( u_k \) and \( \phi \) are the elastic displacement and electric potential, respectively.

3. General solutions for a crack in piezoelectric materials

3.1. Boundary condition of a crack surface

The mechanical boundary condition of cracks in piezoelectric materials is always defined by stress-free crack surfaces. Several electric boundary conditions were proposed in literature. Among these electric boundary conditions, two different conditions are applied widely. Those are permeable and impermeable conditions. For the first one, the electric potential and the normal electric displacement should be continuous across the crack surface
\[
D_3^+ = D_3^- \quad \phi^+ = \phi^-
\]
where the superscripts + and – denote the upper and lower crack surfaces, respectively. This aspect has been supported by McMeeking (1999), and Dunn and Wienecke (1996). Pak (1990), and Suo and Kuo et al. (1992) proposed impermeable conditions on the crack faces
\[
D_3^+ = D_3^- = 0
\]
This paper presents an analysis for the crack problems in piezoelectric materials based on boundary condition (8).

3.2. General solutions for a crack in a three-dimensional infinite piezoelectric solid

Consider a flat crack \( S \) in an infinite three-dimensional piezoelectric solid. A fixed rectangular Cartesian system \( x_i (i = 1, 2, 3) \) is used. The crack is assumed to be in the \( x_1, x_2 \) plane, and normal to the \( x_3 \) axis. Using the fundamental solution of the piezoelectric material, the elastic displacements and the electric potential at an interior point \( p \) can be expressed as (Qin and Noda, 2004)
\[ U_j(p) = - \int_{S^+} T_{IJ}^+(p, Q) \bar{U}_J(Q) ds(Q), \quad I, J = 1, 2, 3, 4 \] (9)

where \( Q \) (or \( Q^+ \)) is a point on the upper crack surface \( S^+ \), and \( T_{IJ}^+(p, Q) = T_{IJ}(p, Q^+) = -T_{IJ}(p, Q^-) \) is the value of the fundamental solutions of the piezoelectric material \( T_{IJ} \) at upper crack surface \( S^+ \), which is related to the Green’s function as follows (Hill and Farris, 1998)

\[ T_{IJ}(p, Q) = E_{\text{ijkl}} \frac{\partial G_{\text{ijkl}}(p, Q)}{\partial \xi_n} n_k \] (10)

where \( n_k \) is the unit outward normal vector, \( \xi_n \) is the coordinate of point \( Q \), \( \bar{U}_J \) is the elastic displacement or electric potential discontinuity, and can be written as

\[ \bar{U}_J = \begin{cases} u_j = u_j^+ - u_j^- & \text{for} \quad J = j = 1, 2, 3 \\ \phi = \phi^+ - \phi^- & \text{for} \quad J = 4 \end{cases} \] (11)

Using solution (9) and constitutive Eq. (3), the corresponding stress and electric displacements are expressed as

\[ \Sigma_{ij}(p) = - \int_{S^+} S_{Kij}^+(p, Q) \bar{U}_K(Q) ds(Q) \] (12)

where the integral kernel is as follows

\[ S_{Kij}(p, Q) = E_{\text{ijkl}} \frac{\partial T_{MK}(p, Q)}{\partial \xi_n} = -E_{\text{ijkl}} \frac{\partial T_{MK}(p, Q)}{\partial \xi_n} \] (13)

### 3.3. Green’s solution

For the transversely isotropic piezoelectric material, the electro-elastic constants can be written as follows:

\[
\begin{align*}
c_{ijkl} &= c_{12}(\delta_{ij}\delta_{kl} + c_{66}(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}) + (c_{13} - c_{12})(\delta_{ij}\delta_{3k}\delta_{3l} + \delta_{ij}\delta_{3l}\delta_{3k} + \delta_{il}\delta_{3j}\delta_{3k} + \delta_{il}\delta_{3k}\delta_{3j}) \\
&\quad + (c_{11} + c_{33} - 2c_{13} - 4c_{44})\delta_{ij}\delta_{kl}31 + e_{13} - e_{15})(\delta_{ij}\delta_{3j} + \delta_{ij}\delta_{3j}) + (e_{33} - e_{13} - 2e_{15})\delta_{3j}\delta_{3j} \\
a_{ij} &= a_{11}\delta_{ij}(c_{33} - a_{13}) \delta_{3j}\delta_{3j}
\end{align*}
\] (14)\( \quad \) (15)\( \quad \) (16)

where \( c_{66} = (c_{11} - c_{12})/2 \). For transversely isotropic piezoelectric, Green’s function can be written as an explicit expression. Here we use the solutions given by Dunn and Wienecke (1996) by a potential method. The governing equations are expressed as

\[
\begin{align*}
u_1 &= \left\{ (c_{13}e_{15} - c_{44}e_{31}) \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right) + [(c_{44} + c_{13})e_{33} - c_{33}(e_{15} + e_{31})] \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right) \right\} g - \frac{\partial \psi}{\partial x_1} \\
u_2 &= \left\{ (c_{13}e_{15} - c_{44}e_{31}) \left( \frac{\partial^2}{\partial x_2^2} + \frac{\partial^2}{\partial x_3^2} \right) + [(c_{44} + c_{13})e_{33} - c_{33}(e_{15} + e_{31})] \left( \frac{\partial^2}{\partial x_2^2} + \frac{\partial^2}{\partial x_3^2} \right) \right\} g + \frac{\partial \psi}{\partial x_2} \\
u_3 &= \left\{ -c_{11}e_{15} \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right) - c_{44}e_{33} \left( \frac{\partial^2}{\partial x_2^2} + \frac{\partial^2}{\partial x_3^2} \right) + [c_{13}(e_{15} + e_{31}) + e_{44}e_{31} - c_{11}e_{33}] \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right) \right\} g \\
\phi &= c_{44}c_{11} \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right)^2 + c_{44}e_{33} \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right) + (c_{11}c_{33} - 2c_{44}c_{13} - c_{13}^2) \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right) \right\} g
\end{align*}
\] (17)

where the potentials \( g \) and \( \psi \) must satisfy following equations:
\[
\left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \frac{1}{v_1^2} \frac{\partial^2}{\partial x_1^2} \right) \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_3^2} + \frac{1}{v_1^2} \frac{\partial^2}{\partial x_3^2} \right) \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \frac{1}{v_2^2} \frac{\partial^2}{\partial x_2^2} \right) \psi = 0
\]

Here \( v_0 = \sqrt{c_6/c_{44}} \), and \(-1/v_1^2, -1/v_2^2, -1/v_3^2\) are the roots of the following cubic equation:
\[
s^3 + \frac{a}{d}s^2 + \frac{b}{d}s + \frac{c}{d} = 0
\]

where
\[
\begin{align*}
a &= c_{11}(a_{11}c_{33} + 2e_{15}e_{33}) - a_{11}c_{13}(e_{13} + 2c_{44}) + c_{44}(a_{33}c_{11} + e_{33}^2) - 2e_{15}e_{13}(e_{31} + e_{15}) \\
b &= c_{33}(a_{11}c_{44} + a_{33}e_{11} + e_{31}(e_{11} + e_{13})) - c_{13}a_{33}(e_{13} + 2c_{44}) + (e_{11} + e_{31})(e_{33}e_{13} - 2c_{13}e_{33}) \\
c &= c_{44}(a_{33}c_{33} + e_{33}^2) \\
d &= c_{11}(a_{11}c_{44} + e_{13}^2)
\end{align*}
\]

If the above Eqs. (18) and (19) are solved for a point charge or force, the Green’s functions can be obtained from the solutions \( u_i \) and \( \phi \).

### 3.3.1. Point force charge

For a unit point charge at point \( \xi(x_1, \xi_2, \xi_3) \), the elastic displacements and electric potential at point \( x(x_1, x_2, x_3) \) can be expressed as
\[
\begin{align*}
u_1 &= \sum_{i=1}^{3} A_i n_i u_{x_1-x_{1_i}} \frac{x_{1_i}}{R_i} \nu_2 = \sum_{i=1}^{3} A_i n_i u_{x_2-x_{1_i}} \frac{x_{1_i}}{R_i} \nu_3 &= \sum_{i=1}^{3} A_i n_i u_{x_3-x_{1_i}} \frac{x_{1_i}}{R_i} \phi &= \sum_{i=1}^{3} A_i n_i \phi_{x_1-x_{1_i}} \frac{x_{1_i}}{R_i}
\end{align*}
\]

where
\[
\begin{align*}
R_i &= \sqrt{(x_1 - x_1)^2 + (x_2 - x_2)^2 + z_i^2} \\
R_i^* &= R_i + z_i, \quad i = 0, 1, 2, 3 \\
\lambda_{x_1}^w &= \left[(e_{13} + c_{44})e_{33} - c_{33}(e_{13} + e_{31})\right] v_i^2 + (c_{44}e_{31} - c_{13}e_{44}) v_i \\
\lambda_{x_2}^w &= -c_{44}e_{33}v_i^2 - [e_{31}(e_{13} + c_{44}) - e_{33}c_{11} + e_{13}e_{15}] v_i^2 - c_{11}e_{15} \\
\lambda_{x_3}^w &= c_{33}c_{44}v_i^2 + [c_{13}(e_{13} + 2c_{44}) - c_{11}e_{33}] v_i^2 + c_{44}e_{11}
\end{align*}
\]

and \( A_i \) is determined by following equations:
\[
\sum_{i=1}^{3} A_i n_i^w = 0 \quad \sum_{i=1}^{3} A_i \frac{n_i^w}{v_i^2} - 1 = 0 \quad \sum_{i=1}^{3} A_i \frac{n_i}{v_i^2} - 1 = \frac{1}{2\pi}
\]

here
\[
\begin{align*}
n_i^w &= 2 [\lambda_{x_1}^w (e_{13} + c_{44}v_i^2) + v_i \lambda_{x_2}^w (e_{33} - c_{33}) + v_i \lambda_{x_3}^w (e_{15} - e_{31})] \\
n_i &= 2 [-\lambda_{x_1}^w (e_{31} + e_{15}v_i^2) + v_i \lambda_{x_2}^w (e_{33} - e_{13}) + v_i \lambda_{x_3}^w (a_{11} - a_{33})]
\end{align*}
\]

### 3.3.2. Point force in \( x_3 \)-direction

For a unit point force in \( x_3 \)-direction at point \( \xi(x_1, \xi_2, \xi_3) \), the elastic displacements and electric potential at point \( x(x_1, x_2, x_3) \) is expressed as
\[
\begin{align*}
\mathbf{u}_1 &= \sum_{i=1}^{3} B_i \lambda_{1i}^w \frac{x_i - \xi_i}{R_i R_i'}, \\
\mathbf{u}_2 &= \sum_{i=1}^{3} B_i \lambda_{2i}^w \frac{y_i - \xi_i}{R_i R_i'} \\
\mathbf{u}_3 &= \sum_{i=1}^{3} B_i \lambda_{3i}^w \frac{1}{R_i'}, \\
\phi &= \sum_{i=1}^{3} B_i \lambda_{1i}^\phi \frac{1}{R_i'}
\end{align*}
\]

where \( B_i \) satisfies following equations

\[
\sum_{i=1}^{3} B_i \lambda_{ii}^w = 0, \quad \sum_{i=1}^{3} B_i \frac{n_i^w}{v_i^f - 1} = \frac{1}{2\pi}, \quad \sum_{i=1}^{3} B_i \frac{n_i^e}{v_i^f - 1} = 0
\]  

**3.3.3. Point force in \( x_1 \)-direction**

For a unit point force in \( x_1 \)-direction at point \( \xi(\xi_1, \xi_2, \xi_3) \), the elastic displacements and electric potential at point \( \mathbf{x}(x_1, x_2, x_3) \) is expressed as

\[
\begin{align*}
\mathbf{u}_1 &= D_0 \left[ \frac{1}{R_0} - \frac{(x_2 - \xi_2)^2}{R_0 R_0'} \right] - \sum_{i=1}^{3} D_i \lambda_{1i}^u \left[ \frac{1}{R_i} - \frac{(x_1 - \xi_1)^2}{R_i R_i'} \right] \\
\mathbf{u}_2 &= (x_1 - \xi_1)(x_2 - \xi_2) \left( D_0 \frac{1}{R_0 R_0'} + \sum_{i=1}^{3} D_i \lambda_{1i}^u \frac{1}{R_i R_i'} \right) \\
\mathbf{u}_3 &= \sum_{i=1}^{3} D_i \lambda_{2i}^w \frac{1}{R_i R_i'} \\
\phi &= \sum_{i=1}^{3} D_i \lambda_{1i}^\phi \frac{1}{R_i R_i'}
\end{align*}
\]

where \( D_i \) satisfies

\[
\begin{align*}
D_0 v_0 + \sum_{i=1}^{3} D_i v_i \lambda_{ii}^u &= 0, \quad \sum_{i=1}^{3} D_i \lambda_{ii}^w &= 0 \\
\sum_{i=1}^{3} D_i \lambda_{1i}^\phi &= 0, \quad D_0 v_0 c_{44} + \sum_{i=1}^{3} D_i \frac{n_i^e}{v_i^f - 1} &= \frac{1}{2\pi}
\end{align*}
\]

here

\[
n_i^w = v_i \lambda_{ii}^u (c_{44} - c_{11}) + \lambda_{ii}^w (c_{44} + c_{13} v_i^r) + \lambda_{1i}^\phi (e_{15} + e_{31} v_i^r)
\]

**4. Hypersingular integral equations**

Using the boundary conditions, the hypersingular integral equations for a flat crack in an infinite transversely isotropic piezoelectric solid can be obtained. Let the source point \( p \) be taken to the upper crack surface and represented by \( P \), using the elastic and electric boundary conditions of the crack surface, the hypersingular integral equations can be obtained as (Qin and Noda, 2004)

\[
\begin{align*}
\mathcal{I}^{\alpha}_{\beta} &= \int_{S^+} \frac{1}{2\pi} \left[ c_{44}^2 D_0 v_0^2 \left( 2\delta_{\alpha \beta} - 3r_3 r_\beta \right) + k_{11} \left( 3r_3 r_\beta - 3r_\beta r_3 \right) \right] \tilde{u}_\beta(Q) ds(Q) = -p_\alpha(P), \quad \alpha, \beta = 1, 2; P \in S^+ \\
\mathcal{I}^3_{\alpha} &= \int_{S^+} \frac{1}{2\pi} \left[ k_{33} \tilde{u}_3(Q) + k_{34} \tilde{\phi}(Q) \right] ds(Q) = -p_3(P), \quad P \in S^+ \\
\mathcal{I}^{3}_{\alpha} &= \int_{S^+} \frac{1}{2\pi} \left[ k_{43} \tilde{u}_3(Q) + k_{44} \tilde{\phi}(Q) \right] ds(Q) = -q_0(P), \quad P \in S^+
\end{align*}
\]

where \( \mathcal{I} \) means that the integral must be interpreted as a finite-part integral, and \( p_\alpha(P) \) and \( q_0(P) \) represent the mechanical and electrical loads on the crack surface due to internal or external loads, and \( k_{ij} \) is determined as
Here the integrals over the crack front elements will be treated as follows. Among these and the other is the internal element group. The integrals over the latter elements can be calculated as paper

\[ k_{11} = \sum_{i=1}^{3} [c_{44}(B_i + D_i v_i) + e_{15} A_i] [c_{44}(v_i \lambda_i' + \lambda_i'') + e_{15} \lambda_i''] \]

\[ k_{33} = \sum_{i=1}^{3} (e_{33} A_i v_i + c_{33} B_i v_i - c_{33} D_i) (-c_{13} \lambda_i' + c_{33} v_i \lambda_i'' + e_{33} v_i \lambda_i'^{\phi}) \]

\[ k_{34} = \sum_{i=1}^{3} (-a_{33} A_i v_i + e_{33} B_i v_i - e_{33} D_i) (-c_{13} \lambda_i' + c_{33} v_i \lambda_i'' + e_{33} v_i \lambda_i'^{\phi}) \]

\[ k_{43} = \sum_{i=1}^{3} (e_{33} A_i v_i + c_{33} B_i v_i - c_{33} D_i) (-e_{31} \lambda_i' + e_{33} v_i \lambda_i'' - a_{33} v_i \lambda_i'^{\phi}) \]

\[ k_{44} = \sum_{i=1}^{3} (-a_{33} A_i v_i + e_{33} B_i v_i - e_{33} D_i) (-e_{31} \lambda_i' + e_{33} v_i \lambda_i'' - a_{33} v_i \lambda_i'^{\phi}) \]

Notice that Eq. (32) is not coupled with Eqs. (33) and (34), and can be solved independently. It means that shear modes are independent of mode I and electric mode. Eqs. (32)–(34) are hypersingular integral equations, and can be numerically solved. Solving these equations, all the unknowns can be obtained. Then the mechanical stress intensity factors corresponding to the crack modes I, II and III as well as the “electric field intensity factor” \( K_{IV} \) are defined as

\[
\begin{align*}
K_I &= \lim_{r \to 0} \sigma_{33}(r, \theta)_{|\theta=0}\sqrt{2r}, & K_{II} &= \lim_{r \to 0} \sigma_{32}(r, \theta)_{|\theta=0}\sqrt{2r}, \\
K_{III} &= \lim_{r \to 0} \sigma_{31}(r, \theta)_{|\theta=0}\sqrt{2r}, & K_{IV} &= \lim_{r \to 0} D_3(r, \theta)_{|\theta=0}\sqrt{2r},
\end{align*}
\]

where \( r \) is the distance from point \( p \), to the crack front point \( Q_0 \), where (3,\( n, \tau \)) are the local coordinates.

5. Numerical technique

Eqs. (32)–(34) are hypersingular integral equations, and can be numerically solved by use of the boundary element method combined with the finite-part integral method (Qin and Tang, 1993, 1997). Assuming that the crack surface \( S^+ \) is divided into a number of quadrangular or triangular elements, Eqs. (32)–(34) can be reduced to a set of linear algebraic equations:

\[
\begin{align*}
\sum_{m=1}^{M} a_{\alpha mn}(P_n, Q_m) \bar{u}_\beta(Q_m) &= -p_\beta(P_n) & \alpha, \beta = 1, 2; & n = 1, \ldots, M; & P_n, Q_m \in S^+ \\
\sum_{m=1}^{M} c_{1mn}(P_n, Q_m) \bar{u}_3(Q_m) + \sum_{m=1}^{M} c_{2mn}(P_n, Q_m) \bar{\phi}(Q_m) &= -p_3(P_n) \\
\sum_{m=1}^{M} d_{1mn}(P_n, Q_m) \bar{u}_3(Q_m) + \sum_{m=1}^{M} d_{2mn}(P_n, Q_m) \bar{\phi}(Q_m) &= -q_0(P_n)
\end{align*}
\]

where \( M \) is the number of the total nodal points located on the surface \( S^+ \), \( P_n \) and \( Q_m \) are the nodal points, \( a_{\alpha mn}, c_{1mn}, c_{2mn}, d_{1mn} \) and \( d_{2mn} \) are the components of coefficient matrix which can be determined by summing all the following integrals relating the reference nodal point \( P_n \) with all the elements in \( S^+ \):

\[
I_m = \int_{S_m} \frac{1}{r} \left[ c_{44} D_0 v_0^2 (2 \delta_{2\beta} - 3 r_{2\beta} r_{\beta}) + k_{11} (\delta_{2\beta} - 3 r_{2\beta} r_{\beta}) \right] \bar{u}_\beta \xi_1 d \xi_2
\]

\[
I_m' = \int_{S_n} \frac{1}{r} \bar{u}_3 \xi_1 \xi_2 d \xi_2
\]

Now the main task is to numerically calculate these integrals. Notice that integrals \( I_m' \) and \( I_m'' \) are similar to integral \( I_m'' \) and can be evaluated similarly. To improve the numerical solution precision, the elements of \( S^+ \) are divided into two groups. One is the crack front element group which is joined with the crack front, and the other is the internal element group. The integrals over the latter elements can be calculated as paper (Qin and Tang, 1993). Here the integrals over the crack front elements will be treated as follows. Among these integrals, there are not only general integrals, but also hypersingular integrals. If the reference point is not in the integrating element, the integrals are normal. For a quadrangular element, \( \bar{u}_i \) is assumed as follows
\[ \tilde{u}_i = \sqrt{\frac{1 - \xi}{2}} \left[ \frac{1}{4} (1 - \zeta)(1 - \eta)u_i^{(d)} + \frac{1}{4} (1 - \zeta)(1 + \eta)u_i^{(c)} + \frac{1}{4} (1 + \zeta)(1 - \eta)c_i^{(a)} + \frac{1}{4} (1 + \zeta)(1 + \eta)c_i^{(b)} \right] \] (42)

where \((\xi, \eta)\) are the local dimensionless coordinates, \(c_i^{(a)}\) and \(c_i^{(b)}\) are unknown constants related to the crack front point \(a\) and \(b\), respectively. The relative integrals can be calculated as normal. It is noticed that \(u_i\) defined by (42) has the \(\sqrt{r}\) behavior near the crack front, which is consistent with the analytical theory (Qin and Noda, 2004). If the reference point \(P_n\) coincides with one of the nodes of the integrating element, the integrals are hypersingular, which can be written as follows. Firstly, it is assumed that the reference point \(Q \in S_{m1}\) or \(Q \in S_{m2}\) as shown in Fig. 1. The displacement discontinuities can be expressed as

\[ \tilde{u}_i = \sqrt{1 - \frac{r}{R}} \left[ L_d \tilde{u}_i^{(d)} + L_a c_i^{(a)} + L_b c_i^{(b)} \right] \quad Q \in S_{m1} \] (43)

\[ \tilde{u}_i = \sqrt{1 - (1 - S_c) \frac{r}{R}} \left[ L_d \tilde{u}_i^{(d)} + L_a \tilde{u}_i^{(c)} + L_b c_i^{(b)} \right] \quad Q \in S_{m2} \] (44)

where \(L_a, L_b, L_c\), and \(L_d\) are the area coordinates of \(S_{m1}\) and \(S_{m2}\), respectively, \(S_c\) is the area coordinate of point \(w\), and \(R\) is the distance between point \(d\) and point \(w\).

The hypersingular integrals related to (43) can be written as

\[ I_{dd} = \int_{S_{m1}} \frac{1}{r^3} \left[ \frac{c_{12}^2 D_0 v_0^2 (2 \delta_{x\beta} - 3 r_{x\beta} r_{y\beta}) + k_{11} (\delta_{x\beta} - 3 r_{x\beta} r_{y\beta})}{1 - \frac{r}{R}} L_d d\xi d\zeta \right] \sqrt{1 - \frac{r}{R}} L_d d\xi d\zeta \] (45)

\[ I_{da} = \int_{S_{m1}} \frac{1}{r^3} \left[ \frac{c_{12}^2 D_0 v_0^2 (2 \delta_{x\beta} - 3 r_{x\beta} r_{y\beta}) + k_{11} (\delta_{x\beta} - 3 r_{x\beta} r_{y\beta})}{1 - \frac{r}{R}} d\xi d\zeta \right] \sqrt{1 - \frac{r}{R}} L_d d\xi d\zeta \] (46)

\[ I_{db} = \int_{S_{m1}} \frac{1}{r^3} \left[ \frac{c_{12}^2 D_0 v_0^2 (2 \delta_{x\beta} - 3 r_{x\beta} r_{y\beta}) + k_{11} (\delta_{x\beta} - 3 r_{x\beta} r_{y\beta})}{1 - \frac{r}{R}} d\xi d\zeta \right] \sqrt{1 - \frac{r}{R}} L_d d\xi d\zeta \] (47)

![Fig. 1. A crack front element.](image-url)
where $\Delta$ is the area of element $S_{m1}$, $L$ is the symbol of principal-value integral, and $S_b$ is the area coordinate of point $w$ on the side $ab$. The hypersingular integrals related to (44) can be analogously treated, here only give the computing formula for the first one

$$I_{dd} = \int_{S_{m1}} \frac{1}{R_0} \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \sqrt{1 - (1 - S_c) \frac{r}{R}} L_d d\xi_1 d\xi_2$$

$$= 2\Delta \int_0^1 \frac{1}{R_0} \left\{ \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \frac{1}{2} (3 + S_c) - 3\sqrt{S_c} + (3 - S_c) \right\} dS_c$$

Secondly, if the reference point $P_n$ infinitely tends to crack front point $a$, link point $a$ with $c$, and the element is divided into two triangular elements $S_{m1}$ and $S_{m2}$ as shown in Fig. 2. The displacement discontinuities can be expressed as

$$\hat{u}_i = \frac{r}{R} S_c \left[ L_c \hat{u}_i^{(d)} + L_{d}\hat{u}_i^{(a)} + L_{bc}\hat{u}_i^{(b)} \right] \quad Q \in S_{m1}$$

$$\hat{u}_i = \frac{r}{R} \left[ L_c \hat{u}_i^{(c)} + L_{d}\hat{u}_i^{(d)} + L_{bc}\hat{u}_i^{(a)} \right] \quad Q \in S_{m2}$$

The hypersingular integrals related to (49) can be written as

$$I_{aa} = \int_{S_{m1}} \frac{1}{R_0} \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \sqrt{1 - (1 - S_c) \frac{r}{R}} L_d d\xi_1 d\xi_2$$

$$= \int_2 \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \sqrt{S_c} d\theta \int_0^{R(\theta)} \frac{1}{r^2} \left[ \sqrt{1 - (1 - \frac{r}{R}) dr} \right]$$

$$= -8\Delta \int_0^1 \frac{1}{R_0} \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \sqrt{S_c} dS_c$$

$$I_{ab} = \int_{S_{m1}} \frac{1}{R_0} \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \sqrt{1 - (1 - S_c) \frac{r}{R}} L_d d\xi_1 d\xi_2$$

$$= 4\Delta \int_0^1 \frac{1}{R_0} \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \sqrt{S_c} (1 - S_c) dS_c$$

$$I_{ac} = \int_{S_{m1}} \frac{1}{R_0} \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \sqrt{1 - (1 - S_c) \frac{r}{R}} L_d d\xi_1 d\xi_2$$

$$= 4\Delta \int_0^1 \frac{1}{R_0} \left[ c_{44} D_0 v_0^2 (2\delta_{x\beta} - 3r_{x\beta} + k_{11}(\delta_{x\beta} - 3r_{x\beta})) \right] \sqrt{S_c} dS_c$$

The hypersingular integrals related to (50) can be analogously treated. For the case that the reference point $P_n$ coincides with point $c$ or infinitely tends to point $b$, the related hypersingular integrals can be analogously treated as above. After computing the integrals over all the elements, Eqs. (37)–(39) can now be solved,
and then all the nodal values of \( \tilde{u}_i \) and \( \tilde{\phi} \) are known, from which the intensity factors at point \( Q_0 \) on the crack front can be calculated as follows:

\[
K_1(Q_0) = \pi \lim_{Q \to Q_0} \left[ k_{33} \tilde{u}_3(Q) + k_{34} \tilde{\phi}(Q) \right] \cdot (2/\rho)^{1/2}
\]

\[
K_{II}(Q_0) = \pi \lim_{Q \to Q_0} \left[ k_{43} \tilde{u}_3(Q) + k_{44} \tilde{\phi}(Q) \right] \cdot (2/\rho)^{1/2}
\]

\[
K_{III}(Q_0) = -\pi k_{11} \lim_{Q \to Q_0} \tilde{u}_n(Q) \cdot (2/\rho)^{1/2}
\]

\[
K_{IV}(Q_0) = \pi c_{44}^2 D_0 v_0^2 \lim_{Q \to Q_0} \tilde{u}_s(Q) \cdot (2/\rho)^{1/2}
\]

where \( (3,n,\tau) \) are the local coordinates.

6. Comparison with elastic isotropic materials

Compared Eqs. (33) and (34) with that for the crack problems in elastic isotropic materials (Qin and Tang, 1993), it can be found that if the term \([k_{33} \tilde{u}_3(Q) + k_{34} \tilde{\phi}(Q)]\) in Eqs. (33) and (54) is replaced with \(E \tilde{u}_3(Q)/8\pi(1 - \nu^2)\), Eqs. (33) and (54) will be changed as following

\[
\frac{E}{8\pi(1 - \nu^2)} = \iint_{S^+} \frac{1}{r^2} \tilde{u}_3(Q)ds(Q) = -p_3(P) \quad P \in S^+
\]

\[
K_1(Q_0) = \frac{E}{8(1 - \nu^2)} \lim_{Q \to Q_0} \tilde{u}_3(Q) \cdot (2/\rho)^{1/2}
\]

Eq. (59) is the same as that for a planar crack in an elastic isotropic material under normal load (Qin and Tang, 1993), and the stress intensity factor (60) will be converted into that for elastic isotropic materials. Similarly, if the term \([k_{43} \tilde{u}_3(Q) + k_{44} \tilde{\phi}(Q)]\) in Eqs. (34) and (55) is replaced as \(E \tilde{u}_3(Q)/8\pi(1 - \nu^2)\), and the electric load \(q_0\) is instead of the elastic load \(p_3\), the electric displacement intensity factor \(K_{IV}\) will be equivalent to the stress intensity factor \(K_1\) for elastic isotropic materials. For mixed mode problems, let that

\[
v = 1 + \frac{c_{44}^2 D_0 v_0^2}{k_{11}}, \quad E = -8(1 - \nu^2)k_{11}
\]

Then, Eq. (33) is turned to

\[
\frac{E}{8\pi(1 - \nu^2)} = \iint_{S^+} \frac{1}{r^2} \left[ (1 - 2\nu)\delta_{\alpha\beta} + 3\nu r^2 r_\alpha r_\beta \right] \tilde{u}_\beta(Q)ds(Q) = -p_\beta(P) \quad \alpha, \beta = 1, 2; \quad P \in S^+
\]

which is the same as that for elastic isotropic materials under shear loads. The formula to evaluate the mixed mode stress intensity factors (56) and (57) can be replaced as

\[
K_{II}(Q_0) = \frac{E}{8\pi(1 - \nu^2)} \lim_{Q \to Q_0} \tilde{u}_n(Q) \cdot (2/\rho)^{1/2}
\]

\[
K_{III}(Q_0) = \frac{E}{8(1 + \nu)} \lim_{Q \to Q_0} \tilde{u}_s(Q) \cdot (2/\rho)^{1/2}
\]

Formulae Eqs. (62) and (63) are the same as those for elastic isotropic materials (Qin and Tang, 1993). Therefore, it can be seen that the intensity factors for piezoelectric materials can be obtained from those for elastic isotropic materials.

7. Numerical results

In order to verify above method and illustrate its application, numerical calculations are performed for a crack embedded in an infinite transversely isotropic piezoelectric solid. The piezoelectric materials PZT-4 and PZT-6B are used for the computations.
7.1. Rectangular crack embedded in an infinite body under normal mechanical loads

Consider a rectangular crack embedded in an infinite transversely isotropic piezoelectric body as shown in Fig. 3. The solid is subjected to normal mechanical load $\sigma_{33}^\infty$ and electrical load $D_3^\infty$ in infinite. In demonstrating the numerical results, the following dimensionless intensity factors will be used

$$ F_I = K_I / \sigma_{33}^\infty \sqrt{b} \quad F_{IV} = K_{IV} / D_3^\infty \sqrt{b} $$

(64)

In case of $a/b = 1$, the number of the total nodes is taken as $19 \times 19$. Dimensionless stress and electric displacement intensity factors are listed in Table 1, and compared with those given by Chen (2003). It is shown that the present results are satisfied. For general cases, the dimensionless stress and electric displacement intensity factors along the crack front $x_2 = \pm b$ are shown in Fig. 4 for different ratios of $a/b$. It can be noticed that the stress intensity factors $F_I$ is only related to the mechanical load $\sigma_{33}^\infty$, and the electric displacement intensity factor $F_{IV}$ is related to the electrical load $D_3^\infty$.

7.2. Elliptical crack embedded in an infinite body

Let us consider an elliptical crack embedded in an infinite transversely isotropic piezoelectric solid as shown in Fig. 5. The solid is subjected to normal mechanical load $\sigma_{33}^\infty$ and electrical load $D_3^\infty$ in infinite. In

Fig. 4. Dimensionless intensity factors $F_I, F_{IV}$ along the crack front $x_2 = \pm b$. 
demonstrating the numerical results, the dimensionless intensity factors are the same as (64). In case of uniform mechanical load and electrical load, the exact solutions of the stress and electric displacement intensity factors have been obtained by Wang and Huang (1995) as follows:

$$F_I = F_{IV} = \frac{(1 - k^2 \cos^2 \varphi)^{1/4}}{E(k)}$$

where $E(k)$ is the complete elliptical integral of the second kind with argument $k^2 = 1 - (b/a)^2$. For different values of ratio $a/b$, Table 2 gives the maximal dimensionless stress and electric displacement intensity factors $F_I, F_{IV} (x_2 = b)$. In case of $a/b = 2$, Table 3 gives the dimensionless stress and electric displacement intensity factors $F_I, F_{IV}$ along the crack front. It is observed that present results are close to the exact solutions given by Wang and Huang (1995). For general cases, the dimensionless stress and electric displacement intensity factors along the crack front are shown in Fig. 6 for different ratios of $a/b$.

Fig. 6. Dimensionless intensity factors $F_I, F_{IV}$ along the crack front.
8. Conclusion

A flat crack embedded in a three-dimensional infinite transversely isotropic piezoelectric solid subjected to mechanical and electrical loads is analyzed by the finite-part integral method and boundary element method.

1) A set of hypersingular integral equations of an impermeable crack in a three-dimensional infinite transversely isotropic piezoelectric solid subjected to mechanical and electrical loads is derived. It can be observed that crack mode II and mode III are coupled, but independent with mode I and electric mode.

2) Based on the analytical solutions of the singular stresses and electrical displacements near the crack front, a numerical method is proposed by the finite-part integral method and boundary element method, where the square root models of the displacement and electric potential discontinuities in the elements near the crack front are applied. The numerical solutions of the stress and electric field intensity factors of some examples are given. The numerical results show that this numerical technique is successful, and the solution precision is satisfied.

3) From the numerical solutions, it is shown that for an impermeable crack, the mechanical loads will generate the stress intensity factors, and the electric load will generate the “electric field intensity factor” $K_{IV}$. Moreover, the dimensionless intensity factors of $K_I$ and $K_{IV}$ are independent of the material constants.

4) It is shown that the numerical values of the dimensionless intensity factors of $K_I$ and $K_{IV}$ are equal to that of the dimensionless stress intensity factor of mode I for elastic isotropic materials. So, in the case of impermeable cracks, the solutions of intensity factors $K_I$ and $K_{IV}$ can be obtained from the stress intensity factor $K_I$ for elastic isotropic materials.
